

HASHING

LEARN MORE

What is Hashing?

- Hashing is the process of mapping of arbitrary size to a fixed size to output a **HASH VALUE**
- Where would we use hash: for storing passwords, for verification of parties sending and receiving communications (digital signatures) or in blockchain.
- Hashing can be created using different algorithms

Hashing

Plaintext

Hash Function

Hashed text

PASSWORD: Apple123\$

HASHED:

**45e905ca6ed448543045ae64ae83
a960f6e4b0a0ce8a1a758fc8e23224
a17552**

FUN FACTS

- **Once you hash an input value, it is generally impossible to reverse it to find the original input (even using computers)**
- **A change in even 1 character of the input text can completely change the output text**
- **There are many algorithms used in hashing**
- **If using the same algorithm, an input text will always produce the same output**
